

GESTIONE DI APPLICAZIONI DI CALCOLO ETEROGENEE CON STRUMENTI DI CLOUD COMPUTING: ESPERIENZA DI INFN-TORINO

S.Bagnasco, D.Berzano, R.Brunetti, M.Concas, S.Lusso

Motivations

- During the last years, the amount of “consumer level” resources devoted to the scientific computing has increased
 - Unfortunately the man power did not !
- It is becoming almost mandatory to consolidate these resources in order to achieve scalability and economy of scale
 - Our Data Centers must assume the role of real “providers” of computing and storage resources, not only of high level services
- The Cloud approach (IaaS) might help to better manage the resources provisioning to the different clients (ie. Grid Sites, small or medium farms, single users)
- Many cloud computing projects are starting both at national and European level
 - A local working cloud infrastructure will also allow to take part to these activities

Our Philosophy

Software Tools

- Cloud management Toolkit (OpenNebula) (V 3.6)
 - Open Source stack with a wide user community
 - Modular architecture
 - Already satisfies most of the requirements in term of functionalities
 - Easy to customize (mostly shell and ruby scripts)
- Backend storage (GlusterFS) (V 3.3)
 - Easy to setup in a basic configuration
 - Robust
 - Scalable
- VM network management (OpenWRT)
 - Light-weighted Linux distribution for embedded systems with tools for the network configuration and management

Multipurpose storage: GlusterFS

- GlusterFS mimics many RAID functionalities at filesystem level by aggregating single “bricks” on different machines:
 - Modes: distributed, replicated, striped (can be combined)
- Our use cases:
 - VM image repository: one brick exported
 - System datastore: replicated on two servers for redundancy. Replica is synchronous, self-healing enabled. Continuous r/w occurs
 - Experiment data: pool of disks aggregated (~50 TB). Very high throughput towards many concurrent clients
- Horizontal scalability:
 - no master host → all synchronizations are peer-to peer
- Easy management:
 - On-line addition, removal, replacement of bricks

Clusters

Depending on which kind of host has to be instantiated, we identified two types of clusters

Services

- VMs providing critical services with in/outbound connectivity, public IP, live-migration etc.. but with limited disk I/O

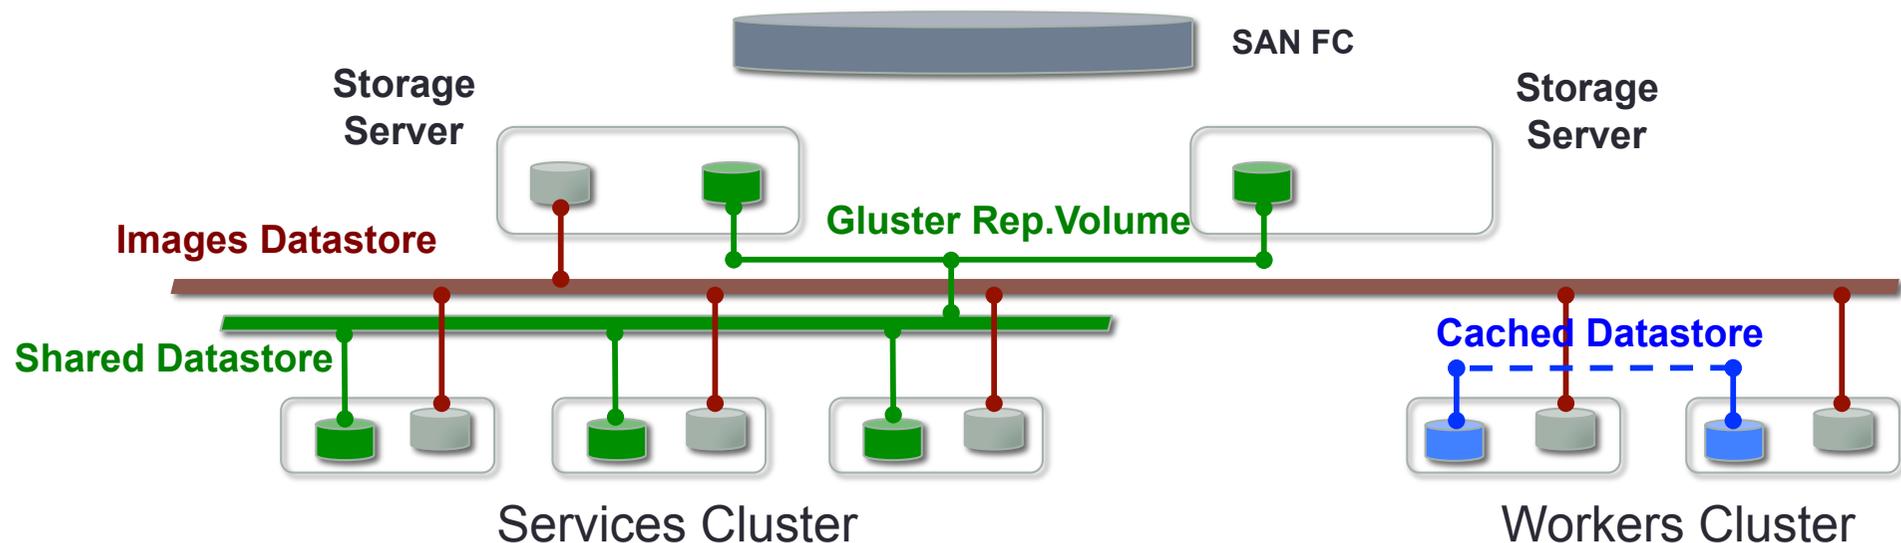

Workers

- VMs providing non critical computing services (like WNs) with private IP only but requiring high disk I/O capacity.

These two classes have been provided with different types of backend storage (“Datastores” in the OpenNebula terminology) in order to optimize the performances and satisfy the above requirements.

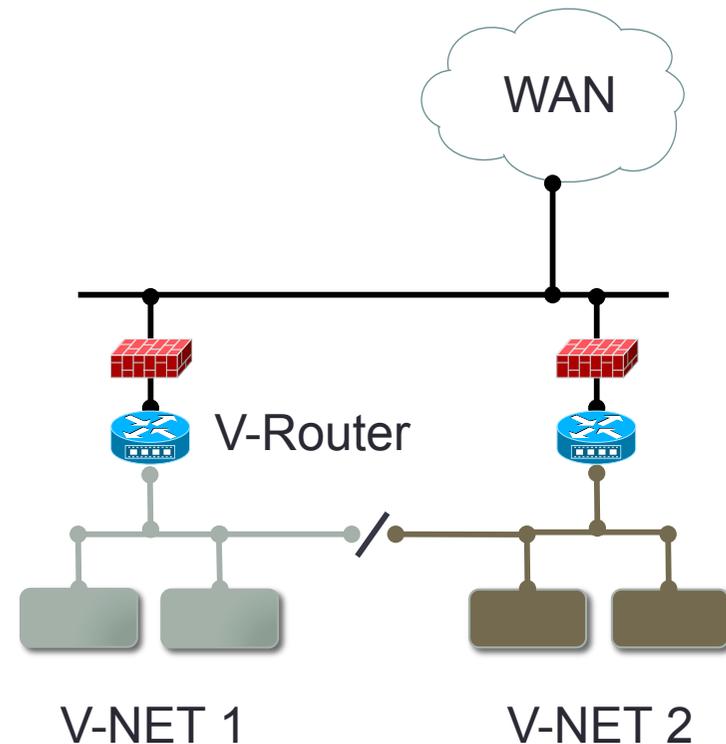

Backend Storage

- **Two storage servers with 10Gbps interface provide some of the LUNs through GlusterFS**
 - **Services System Datastore** is shared to allow live migration of the machines.
 - **Workers System Datastore** is local to the hypervisors disks in order to increase I/O capacity. Images are cached locally to increase startup speed
 - An ad-hoc script synchronizes the local copies using a custom “torrent-like” tool when new versions of the images are saved
 - All the virtual machines run on RAW or QCOW file images.

Networking

- Network Isolation (Level 2)
 - Each user has its own Virtual Network, isolated using “etables” rules defined on the hypervisor bridge (OpenNebula V-net driver takes care of this).
- Virtual Routers (Level 3)
 - We prepared a light-weighted VM image (1 CPU/150 MB Ram) starting from a linux distro designed for embedded systems (OpenWRT).
 - DHCP Server, DNS Server, NAT
 - Firewalling/Port Forwarding
 - This provides the user with a dedicated fully featured class-C network whose connectivity remains under our control (the user has no access to the V-Router)

V-Router GUI

The screenshot displays the V-Router GUI interface. At the top, there is a navigation bar with the URL `cloud-gw-211.to.infn.it` and menu items for Status, System, Network, and Logout. Below this, the main content area is divided into several sections:

- Cache Status:** Shows 'Cached' at 4052 kB / 148456 kB (2%) and 'Buffered' at 576 kB / 148456 kB (0%).
- Network:** Displays IPv4 WAN Status for interface `eth1`. The configuration includes:
 - Type: static
 - Address: 193.205.66.211
 - Netmask: 255.255.255.128
 - Gateway: 193.205.66.254
 - DNS 1: 192.84.137.2
 - DNS 2: 192.84.137.1
 - Connected: 28d 2h 57m 43s
- Active Connections:** Shows 58 / 16384 (0%).
- DHCP Leases:** A table listing active leases:

Hostname	IPv4-Address	MAC-Address	Leasetime remaining
node-001	172.16.5.1	02:00:ac:10:05:01	7h 5m 27s

The screenshot displays the 'Port Forwards' configuration page in the V-Router GUI. The page title is 'Port Forwards' and it features a table with columns for Name, Protocol, Source, Via, Destination, Enable, and Sort. Below the table are several rows of port forwarding rules, each with 'Edit' and 'Delete' buttons.

Name	Protocol	Source	Via	Destination	Enable	Sort
ssh-to-fisrt-node	TCP	From <i>any host</i> in wan	To <i>any router IP</i> at port 22	Forward to IP 172.16.5.1, port 22 in lan	<input checked="" type="checkbox"/>	+
httpd-to-node001	TCP	From <i>any host</i> in wan	To <i>any router IP</i> at port 80	Forward to IP 172.16.5.1, port 80 in lan	<input checked="" type="checkbox"/>	+
swift-to-node001-1	TCP	From <i>any host</i> in wan	To <i>any router IP</i> at port 443	Forward to IP 172.16.5.1, port 443 in lan	<input checked="" type="checkbox"/>	+
swift-to-node001-2	TCP	From <i>any host</i> in wan	To <i>any router IP</i> at port 8080	Forward to IP 172.16.5.1, port 8080 in lan	<input checked="" type="checkbox"/>	+
swift-to-node001-3	TCP	From <i>any host</i> in wan	To <i>any router IP</i> at port 6000	Forward to IP 172.16.5.1, port 6000 in lan	<input checked="" type="checkbox"/>	+
swift-to-node001-4	TCP	From <i>any host</i> in wan	To <i>any router IP</i> at port 6001	Forward to IP 172.16.5.1, port 6001 in lan	<input checked="" type="checkbox"/>	+

Stakeholders

Grid T2 Site

- All the Grid services (CE,SE,BDII ecc..) + xx job slot (WNs contextualize at boot time)

ALICE Analysis Facility (PROOF)

- Shares the resources with the Grid T2, nodes are instantiated on-demand and contextualize at boot time

M5L-CAD

- INFN & diXit spin-off for the automatic analysis of tomographic images
- Self provisioning of VM

BES III Experiment

- Research group testing some ad-hoc WNs to understand how to use the Grid for their computing needs
- Plan to have a full BES-III Tier-2 next year

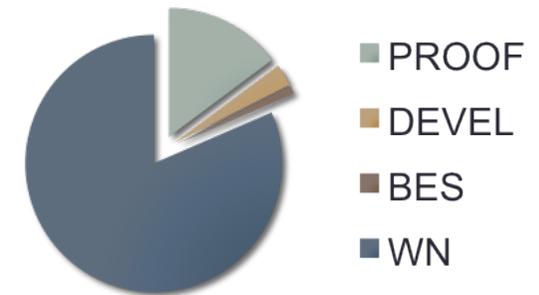

Development Machines

- DGAS accounting development.
- Test of various services (ie. new versions of OpenNebula itself)

Resources

Physical Nodes:

- 31 host (KVM hypervisors)
 - 27 dedicated to “Workers” cluster
 - 4 dedicated to “Services” cluster
- 1 cloud controller (master)

Storage:

- 2 storage server with 10Gbps Ethernet interface (≈ 20TB SAN frontend)

About 650 cores and growing

Remote VM Control

The screenshot displays the OpenNebula Sunstone web interface. The browser address bar shows `https://one-master.to.infn.it`. The page title is "OpenNebula Sunstone" and the user is logged in as "oneadmin". The main navigation menu includes Dashboard, System, Virtual Resources, Virtual Machines (selected), Templates, Images, Infrastructure, Clusters, Hosts, Datastores, Virtual Networks, and Marketplace. The main content area shows a table of virtual machines. A modal window titled "VNC connection" is open, displaying a terminal session for VM "one-2307". The terminal output shows the VM's OS version and kernel information, followed by a login prompt.

ID	Username	Group	State	Host	IP
2280	oneadmin	oneadmin	EMIO2 RUNNING	one-kvm-02	192.168.3.27
2294	oneadmin	oneadmin	EMIO2 RUNNING	one-kvm-27	192.168.3.3

```
VNC connection
Connected (encrypted) to: QEMU (one-2307)
Send CtrlAltDel

Future Developments

- Test the possibility to turn to some form of hybrid/public/distributed infrastructure using:
 - OCCI Interface (preferred choice due to interoperability with other cloud stacks)
 - OpenNebula “Zones”
- Study the integration of the OpenNebula Authn/Authz system in a VO context or using federated authentication mechanisms.
- Explore the GlusterFS *UFO* (Object Storage) to provide a “DropBox-like” storage to the users.
- Participate in the INFN projects aimed to develop a higher level distributed infrastructure

Conclusions

- The experience of the setup of a private cloud in the context of the INFN-Torino computing center using OpenNebula + GlusterFS has been positive.
- The infrastructure is now running production services and the idea is to extend it and make it a “service” for all the local computing needs.
- We are very interested to collaborate in every activity aimed to develop and test the different cloud stack interoperability using:
 - Common images repositories (usage criteria, validation)
 - Standard interfaces (OCCI)
 - Federated Authn/Authz systems
- ..and to participate in the upcoming effort to explore clouds as a resource for scientific computing
 - And possibly to build a federated higher-level infrastructure

THANK YOU

User Management

Users and Groups

- Now
 - Users have a simple Username/Password account on the cloud UI and are assigned to groups
 - User groups have access to selected VM images, V-net etc..
- Future
 - Moving to some stronger Authn/Authz method (Shibboleth, X509 etc..)

Quotas

- The amount of resources that a given group can instantiate is limited by quotas on CPU number, RAM and storage.

Customizations

- Most of the requirements of our use cases were already satisfied by the OpenNebula features
- Whenever we needed something more, we tried to stay “mainstream” adding (and not modifying) some of the administrative tools, but always using the OpenNebula APIs
 - Slightly modified the “onevm” command in order to provide some more information
 - Prepared some ad-hoc contextualization scripts to manage the automatic adding/removing of Grid WNs or PROOF nodes
 - Prepared the synchronization script “torrent-like” to manage the images in the Cached Datastore (Workers cluster)

Datastores

- Represent the real “backbone” of the cloud infrastructure, providing the two main components:
 - Virtual machine images repository
 - **Images Datastore** : Simple GlusterFS Volume mounted on all hypervisors
 - Storage for the running virtual machine images
 - **System Datastore** : Replicated GlusterFS Volume available on all “Services” hypervisors
 - **Cached Datastore** : Local storage on all “Workers” hypervisors
 - VMs run on top of a qcow snapshot.
 - An ad-hoc script takes care to synchronize the local copies using rsync (scpwave) when new versions of the images are saved
